I. EXECUTIVE SUMMARY

There are many schools across the globe in which they are still heavily reliant on paper to keep track of their important data. This is not ideal as they degrade, and the risk of losing them in an incident such as natural disaster is very likely with the chance of recoverability being near zero. Migrating to a digital-based database will solve the problem entirely provided it is properly implemented. The solution that we are pushing will be useful since it is open source (it costs \$0 for them to use). The system we offer provides core functionality that is likely to apply to all schools, and each school needs to tweak it to adopt a database system each one of them really wants.

II. BACKGROUND

Many primary education institutes around the world, especially developing countries, still use paper to keep important data. This itself is a problem because physical matter degrades over time. Schools around the world try to organize their data in a neat manner but due to a lack of resources schools have around the world they do not have the capability to organize the data. By managing data from students for each single year, the schools must create new data for every student that joins and students who leave the school the data needs to be destroyed or transferred. This results in data being misplaced or mixed up which becomes very problematic when transferring the records to other schools.

In addition, natural disasters can damage paper data. This makes backing up data very hard because of the ridiculous amount of work trying to regather the lost data. Even if the paper data were to be recovered, the damage caused either directly or indirectly from natural disasters can make the written data hard to transcribe or even impossible.

III. PROBLEM STATEMENT

Natural disasters occur everywhere, almost every minute. This puts schools in the vicinity of the danger at great risk of potentially losing all their important data permanently. Not only this, attacks from burglary may also pose a threat to students' private information. While it is something that people must face with, technology has been evolving for many decades now that it is long overdue for those schools to be modernized for both ease of access and safety perspectives.

IV. PURPOSE AND MOTIVATION

One of the main reasons for using a digital database is that it solves the issue of storing paper data. You won't need to worry about digital database degrading because it is stored in the computer. That data can be backed up in a cloud server to be on the safer side. In addition, institutions will not need to pay for using digital databases and storing data inside the database because there are programs and services that are free and open source.

Another main reason for using a digital database is so that the data can easily be transferred to other schools or institutions without worrying about the data being disorganized. With multiple primary education institutes around the world using the same kind of database schools do not need to spend extra time converting the data and can avoid having anomalies with the student data such as having record for two students with the same name.

V. DESIGN PROCESS

5.1. REQUIREMENTS GATHERING

The primary goal of this database is to store data regarding students and staff members. When gathering this information, we focus on information that the students will need when attending a school along with crucial data that is needed for the courses the students take.

We've gathered the type of information that a school should have. Obviously, we need students and staff for a school. So, we must create tables for students and staff and the information about them.

Attendance is required for primary schools, so we designed a table that stores a student's attendance, whether they were absent or present.

Now we need to determine the type of absence because there are multiple reasons why a student may be absent for a class. With the students and staff information table created, at least the conceptual design, we also need courses that these students take and who teaches these courses. That's where we create the course catalog. We also realize that these courses must have a prerequisite for students to take these courses. As a result, we must create a table for the course prerequisites for the course offerings.

A course must have a location. So that's where we must create a table for locations and their maximum capacity. However, there would be a limit on how many people can take a course

Now that we gathered the types of data to be stored in our school database, below is the initial table data:

*STUDENT_INFORMATION = STUDENT_ID, LAST_NAME, FIRST_NAME,
DATE_OF_BIRTH, ADMITTED_DATE, STUDENT_ADDRESS, SEX*

STUDENT_GRADE_YEAR = STUDENT_ID, GRADE_YEAR

STUDENT_COURSE = STUDENT_ID, COURSE_ID, TERM, FINAL_GRADE

STUDENT_ATTENDANCE = STUDENT_ID, DATE, ABSENCE_ID, REASON

ABSENCE_TYPES = ABSENCE_ID, ABSENCE_TITLE, DESCRIPTION

*STAFF_INFORMATION = INSTRUCTOR_ID, ROLE_ID, LAST_NAME, FIRST_NAME,
SSN, SALARY, PHONE_NUMBER, DATE_OF_BIRTH, ADMITTED_DATE,
STAFF_ADDRESS*

STAFF_ROLE = ROLE_ID, ROLE_TITLE, ROLE_DESCRIPTION

*COURSE_CATALOG = COURSE_ID, ASSIGNED_INSTRUCTOR_ID,
REQUIREMENT_ID, LOCATION, TITLE, DESCRIPTION, DEPARTMENT_TITLE,
DEPARTMENT_DESCRIPTION*

*COURSE_REQUIREMENTS = REQUIREMENT_ID, REQUIREMENT_TITLE,
REQUIREMENT_DESCRIPTION*

LOCATION = LOCATION_ID, LOCATION_NAME, MAX_CAPACITY

Highlighted items are some of the fields from the table that are not mandatory in order for the database to function.

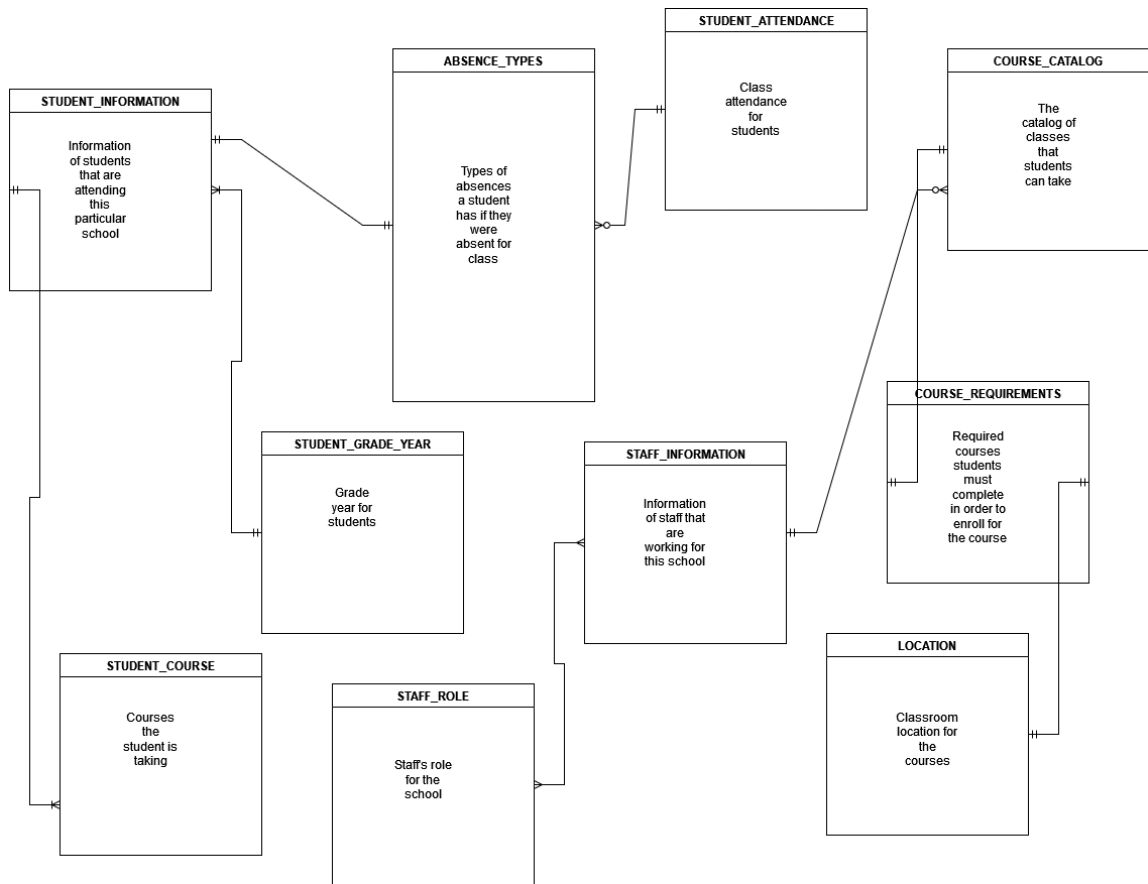

In addition to the table data, we created three views based on the individual's role in that school as follows:

Headmaster: read general information about students or staff and their respective information

Teacher: read and write access of student's information on specific class (needs filter by teacher's embedded class)

Student: read access of student's course history (needs filter by student's ID)

Initial Table Diagram:

5.2. CONCEPTUAL DESIGN

5.2.1. BUSINESS RULES

- i. Titles and descriptions need to match (e.g., role titles and role description must match).

- ii. Instructors must be experienced (must be born no later than today's date, 1997).
- iii. The maximum number of students for a course is based on the room capacity.
- iv. Locations are based off a single country for consistency per database, meaning students and staff must be from the same country.
- v. The information that is visible is based on the views (e.g., students can only see their own data, staff can see their students' information and their own information as well, etc.).

5.2.2. DESIGN SCREEN

The design screens are the views that will be represented on the MySQL workbench (note that this is after we finished the normalization process of the tables and implement the physical design):

5.3. LOGICAL DESIGN

We'll need to normalize the data from the conceptual design to get it to at least 3NF. To get to at least 3NF, we need to get it to 1NF, which is to remove any multivalued data. But first, we need to create a primary key for each entity. Any attribute that has the word ID should be the key for each entity. However, STAFF_INFORMATION has two attributes that have ID in it: INSTRUCTOR_ID and ROLE_ID. Since this table is for staff, we decided to use INSTRUCTOR_ID for the primary key.

Now that we figured out the primary keys for each entity, we remove STUDENT_ADDRESS from STUDENT_INFORMATION table and create a new table called STUDENT_ADDRESS using STUDENT_ID as the primary key. Furthermore, we create new attributes NUMBER, STREET_ADDRESS, CITY, STATE_OR_PROVINCE, COUNTRY, and ZIP_CODE for STUDENT_ADDRESS. The same goes for STAFF_INFORMATION, where the entities are the same as STUDENT_ADDRESS for the STAFF_ADDRESS table.

Now that the table is in 1NF, we'll need to get it to 2NF. However, it's already in 2NF because all entities are fully dependent on the primary key. However, we still need to get it to 3NF because there are some transitive dependencies that are found in our design.

To achieve 3NF, we need to separate DEPARTMENT_TITLE and DEPARTMENT_DESCRIPTION from COURSE_CATALOG. While DEPARTMENT_TITLE is dependent on COURSE_ID, DEPARTMENT_DESCRIPTION is dependent on DEPARTMENT_TITLE even though DEPARTMENT_TITLE is not a key. We create a new table called

DEPARTMENT and give it a primary key called DEPARTMENT_ID. DEPARTMENT_ID also becomes a foreign key for the table COURSE_CATALOG.

Below are the normalized primary keys, foreign keys, and the ERD of the logical design:

STUDENT_INFORMATION = STUDENT_ID (PK), LAST_NAME, FIRST_NAME, DATE_OF_BIRTH, ADMITTED_DATE, SEX

STUDENT_ADDRESS = STUDENT_ID (PK), NUMBER (PK), STREET_ADDRESS (PK), CITY (PK), STATE_OR_PROVINCE (PK), COUNTRY (PK), ZIP_CODE (PK)

STUDENT_GRADE_YEAR = STUDENT_ID (PK), GRADE_YEAR (PK)

STUDENT_COURSE = STUDENT_ID (PK), COURSE_ID (PK), TERM (PK), FINAL_GRADE

STUDENT_ATTENDANCE = STUDENT_ID (PK), DATE (PK), ABSENCE_ID (FK)

ABSENCE_TYPES = ABSENCE_ID (PK), ABSENCE_TITLE, DESCRIPTION

STAFF_INFORMATION = INSTRUCTOR_ID (PK), ROLE_ID (FK), LAST_NAME, FIRST_NAME, SSN, SALARY, PHONE_NUMBER, DATE_OF_BIRTH, ADMITTED_DATE

*STAFF_ADDRESS = STAFF_ID (PK), NUMBER (PK), STREET_ADDRESS
(PK), CITY (PK), STATE_OR_PROVINCE (PK), COUNTRY (PK), ZIP_CODE
(PK)*

STAFF_ROLE = ROLE_ID (PK), ROLE_TITLE, ROLE_DESCRIPTION

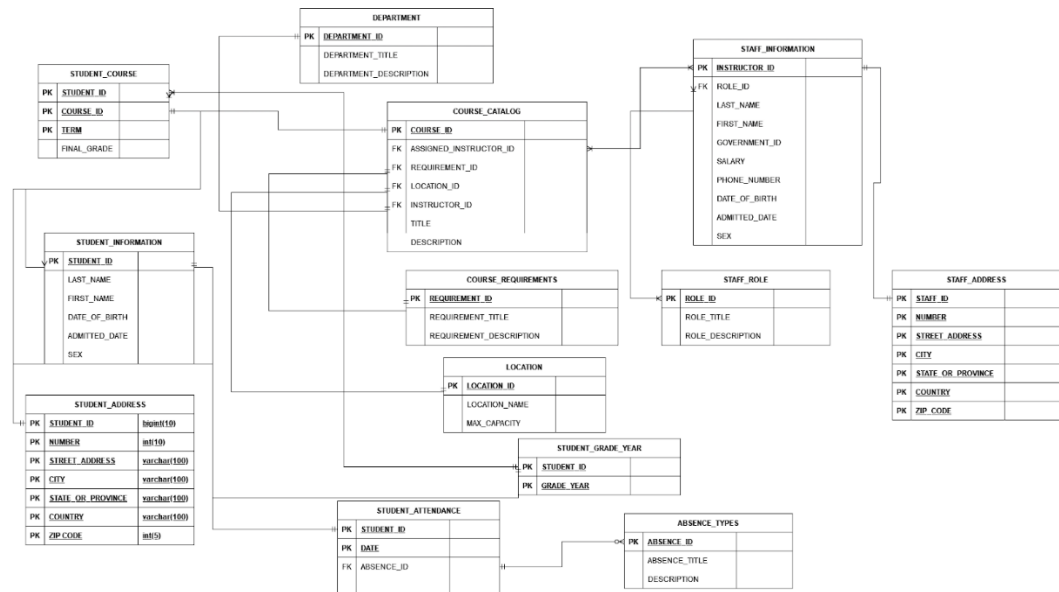

*DEPARTMENT = DEPARTMENT_ID (PK), DEPARTMENT_TITLE,
DEPARTMENT_DESCRIPTION*

*COURSE_CATALOG = COURSE_ID (PK), ASSIGNED_INSTRUCTOR_ID
(FK), REQUIREMENT_ID (FK), LOCATION (FK), DEPARTMENT_ID (FK),
TITLE, DESCRIPTION*

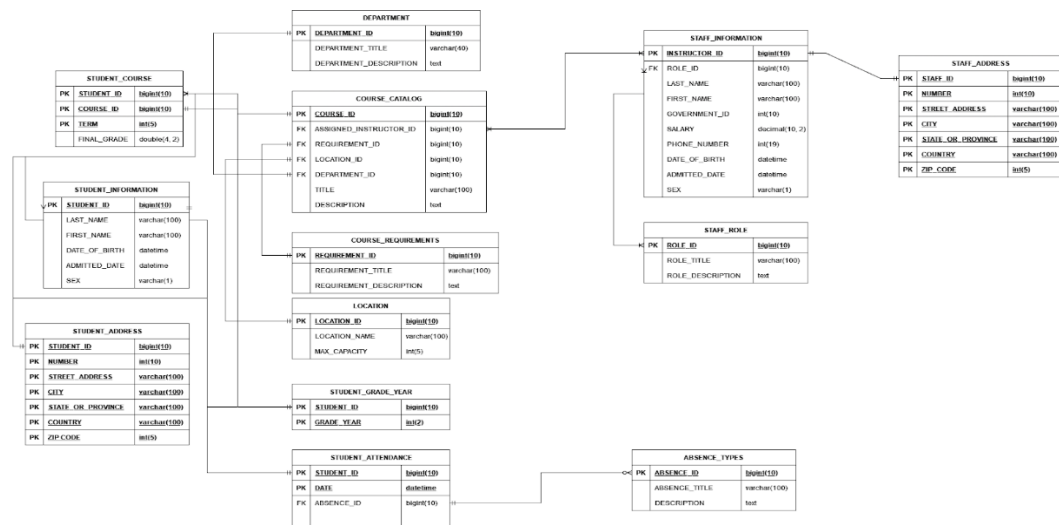

*COURSE_REQUIREMENTS = REQUIREMENT_ID (PK),
REQUIREMENT_TITLE, REQUIREMENT_DESCRIPTION*

LOCATION = LOCATION_ID (PK), LOCATION_NAME, MAX_CAPACITY

Logical Design in 3NF:

ERD Diagram:

5.4. PHYSICAL DESIGN

The physical design's ERD is like the logical design, but we added the data types for all the entities. The primary key values are always an int, unique, and not null because they represent the relationship for the tables. Entities like DATE_OF_BIRTH and ADMITTED_DATE for STUDENT_INFORMATION

and STAFF_INFORMATION table are represented by DATETIME. The rest is self-explanatory.

We also added a check constraint to check whether SEX for STUDENT_INFORMATION and STAFF_INFORMATION is M or F.

As for the data to insert, the views below show the data that was inserted for each table. Each table has a minimum of six entries. All the commands to create the tables and insert the data are done with MySQL.

Below are some of the many tables we have populated.

Student Information Table:

| STUDENT_ID | LAST_NAME | FIRST_NAME | DATE_OF_BIRTH | ADMITTED_DATE | SEX |
|------------|-----------|------------|---------------------|---------------------|-----|
| 68391 | Cabling | John | 2006-10-03 00:00:00 | 2020-08-19 00:00:00 | M |

VI. IMPLEMENTATION AND TEST REPORT

6.1. TESTING METHOD

By populating the tables with more students, staff, and courses, we can move on to the testing process. The purpose of this is to see if all the queried data returns all inserted data as intended. By using the SQL command `SELECT FROM (Table)`, we can return all the data from the table.

6.2. POPULATED TABLES

Student Information table:

The screenshot shows a database management interface. At the top, a SQL query is entered in a text area:

```
1 • Use schooldb;  
2  
3 • SELECT * FROM STUDENT_INFORMATION;  
4
```

Below the query, the results are displayed in a table. The table has the following columns: STUDENT_ID, LAST_NAME, FIRST_NAME, DATE_OF_BIRTH, ADMITTED_DATE, and SEX. The results are as follows:

| STUDENT_ID | LAST_NAME | FIRST_NAME | DATE_OF_BIRTH | ADMITTED_DATE | SEX |
|------------|-----------|------------|---------------------|---------------------|-----|
| 68391 | Cabling | John | 2006-10-03 00:00:00 | 2020-08-19 00:00:00 | M |
| 68392 | Garcia | Rick | 2007-08-12 00:00:00 | 2021-08-21 00:00:00 | M |

GOVERNMENT_ID to represent residents of that country.

Staff Role table:

The screenshot shows the MySQL Workbench interface. At the top, the 'Query 1' tab is active. The SQL editor contains the following query:

```
1 • Use schooldb;
2
3 • SELECT * FROM STAFF_ROLE;
4
5
```

Below the editor, the 'Result Grid' tab is selected, displaying the results of the query. The table has three columns: ROLE_ID, ROLE_TITLE, and ROLE_DESCRIPTION. The results are as follows:

| ROLE_ID | ROLE_TITLE | ROLE_DESCRIPTION |
|---------|----------------------------|--|
| 83745 | 7th grade Math Teacher | Teacher for 7th grade math |
| 83746 | 7th grade Science Teacher | Teacher for 7th grade math |
| 83747 | 7th grade History Teacher | Teacher for 7th grade math |
| 83748 | 8th grade Math Teacher | Teacher for 8th grade math |
| 83749 | 8th grade Science Teacher | Teacher for 8th grade math |
| 83750 | 8th grade History Teacher | Teacher for 8th grade math |
| 83751 | Headmaster | Headmaster |
| 83752 | Janitor | Daytime janitor |
| 83753 | Advisor | advisor for 8th grade students with last names ... |
| 83754 | 9th grade Math Teacher | Teacher for 9th grade math |
| 83755 | 9th grade Science Teacher | Teacher for 9th grade math |
| 83756 | 9th grade History Teacher | Teacher for 9th grade math |
| 83757 | 10th grade Math Teacher | Teacher for 10th grade math |
| 83758 | 10th grade Science Teacher | Teacher for 10th grade math |
| 83759 | 10th grade History Teacher | Teacher for 10th grade math |
| NULL | NULL | NULL |

At the bottom of the window, the status bar shows 'STAFF_ROLE 38'.

This shows the role of the staff and the description.

Student Attendance table:

Query 1 x

Apply Revert

This shows the courses the students took, the term taken and the final grade that they received.

VII. DEPLOYMENT

Our database is deployed online on DigitalOcean. The following steps show how the school database is created:

1. Create Digital Ocean account.
2. Select “New Project”.
3. Name the new project and provide a brief description.
4. Select “Create Managed Database”.
5. Select the data center that will host the database live and the engine (MySQL).
6. Select the plan appropriate for the scale of the project.
7. Choose a unique database cluster name if desired.
8. Select “Create Database Cluster”.
9. Wait several minutes for the server to initialize and set everything up.
10. Collect the connection link and password that will be used to access the database from RDBMS.
11. Open client-based RDBMS (e.g., MySQL Workbench) and fill in the connection credentials (username, password, host link, port, and SSL mode).
12. Connect to the database and start creating tables.

To connect to an existing online database:

1. Open client-based RDBMS (e.g., MySQL Workbench) and fill in the connection credentials (username, password, host link, port, and SSL mode).
2. Connect to the database and start creating extra tables as necessary.
3. To entry data, use standard CLI on the RDBMS.

VIII. CONCLUSION

Our school database has been executed on DigitalOcean. We've explained the steps on how to implement the database through DigitalOcean in the previous step. The overall development from the conceptual design to the deployment went within our favor. If we have the credentials for the database, we can access the database remotely. Due to time constraints, we weren't able to create a GUI for the database.

Going through the design process, this relational database is a more effective way for institutes in developing countries to store data regarding their students, staff, courses, and other important data. Not only that, but the deployment of this relational database through DigitalOcean also provides a cleaner way access and back up data in the events of any natural disaster to occur. The steps to create and deploy the database may be daunting, but this is a far better way to store data and we hope institutes in developing countries will follow along.
